

A METHOD OF MANUFACTURING AN ELECTRONIC DEVICE

BACKGROUND OF THE INVENTION

Field of the Invention

5 The present invention relates to a method of manufacturing an electronic device and more particularly to a method of manufacturing an electronic device equipped with a semiconductor integrated circuit, including IC cards, valuable papers, contactless identification devices and the like.

10 Description of the Prior Art

 Recently, some electronic devices are estimated to have a promised potential that these devices, including IC cards equipped with an IC chip, a tag, and an identification devices by radio frequency technology, may incorporate a functionality
15 in addition to the recognition of bar codes of the prior technology.

 Now an exemplary method of manufacturing an IC card in accordance with the prior technology will be described with reference to Figs. 14 (a) to 14 (c). As shown in Fig. 14 (a),
20 a thin IC chip 17 will be sucked from a pellet case 142 by means of a vacuum absorber 141. Then the picked up IC chip 17 will be transferred on an IC card substrate 15 (base film) having some adhesive paste applied thereon and pressed on it to fix thereon (see Fig. 14 (b)). Thereafter the IC chip 17 attached
25 will be covered by a covering sheet 19, as shown in Fig. 14 (c).

Another example of attaching a semiconductor chip onto a base film is disclosed in the Japanese Patent Application Laid-Open No. Hei 08-316194. The method disclosed therein will be described with reference to Figs. 2 (a) to 2 (c). In this example, as shown in Fig. 2 (a), a plurality of semiconductor chips 17 having an antenna 16 is attached on a supporting sheet, these chips 17 will be pushed on a base film 15 having paste material 14 by means of a press head 21. Thereby the thin IC chips will be transferred and fixed on the film base as shown in Fig. 2 (b). Fig. 2 (c) is a cross-section indicating the chip and film encapsulated by an adhesive material 18 thereafter.

In the prior techniques as have been described above, the productivity is low because an IC chip is attached one at a time on a substrate. For example, in the method shown in Figs. 14 (a) to 14 (c), the improvement of productivity will be limited because each chip is sucked and transferred one at a time. In the prior method shown in Figs. 2 (a) to 2 (c), the press head is registered with each of chips to press one by one, the mechanism of assembly machine will become complex. In addition, a certain gap between two adjoining chips will be required during the transfer. This results in a difficulty of lowering the manufacturing cost.

In addition, if the thickness of IC chips to be delivered is for example equal to or less than 10 micrometers, the IC chip will be curled due to the internal stress of the semiconductor

material. Thus, this may cause a damage in the chip, which will deform from a curled shape to a plane shape when sucked. In addition, since the chip is very thin, the sucking force of the vacuum sucker may result in a local deformation of the chip, leading to a change of device characteristics by the stress applied to the devices on the chip.

SUMMARY OF THE INVENTION

The present invention has been made in view of the above circumstances and has an object to overcome the above problems and to provide a method of manufacturing an electronic device, suitable for mass production of such devices equipped with a semiconductor integrated circuit.

Another object of the present invention is to provide a method of manufacturing an electronic device, with a lower cost and a higher reliability.

Yet another object of the present invention is to provide a method of manufacturing an IC chip suitable for the method of manufacturing an electronic device as have been described above and ease in processing.

To achieve the object and in accordance with the purpose of the invention, as embodied and broadly described herein, this invention comprises a method of manufacturing an electronic device, comprising the steps of: providing a frame having a plurality of openings on a substrate to be mounted with a

semiconductor device, each opening has a dimension suitable to the semiconductor device; providing a plurality of semiconductor devices to the frame to seat one in each of the openings; and fixing the semiconductor devices to the substrate.

5 By means of a frame having a plurality of openings, a number of semiconductor devices may be supplied to predetermined positions on the substrate at once.

By means of a film-based substrate as the substrate, mass production will be facilitated. In addition, the productivity
10 will be further improved by rolling up and rewinding the base film.

By means of a paper sheet as substrate, the product may be used for the valuables.

To achieve the another object and in accordance with the
15 purpose of the invention, as embodied and broadly described herein, this invention comprises a method of manufacturing an electronic device, comprising the step of: using a thinner IC chip than 30 micrometers for the semiconductor device.

By using a thin film chip, the reliability thereof will
20 be improved due to the strength with respect to the bending stress. The strength with respect to the bending stress may be significant when the thickness is equal to or less than 10 micrometers.

To achieve effectively the yet another object and in accordance with the purpose of the invention, as embodied and
25 broadly described herein, this invention comprises a method of

manufacturing an electronic device, comprising the step of:
providing a supporting dowel member on the surface or on the
backside or on both sides of a thin IC chip.

5 A support member will improve the resistance to the external
stress to facilitate the handling. In particular, the fracture
of chips during supplying the thin IC chip onto the frame may
be considerably reduced. The thin IC chips will also be placed
with a significant certainty on the openings of the frame.
Furthermore, the curling of chips when the chips are thinner
10 may be prevented or suppressed.

By forming the semiconductor device in a shape of cube,
the resistance to the external stress will be increased to improve
the reliability. In particular, the breakage of corner of the
chip will be significantly reduced by forming the maximum
15 dimension of 0.5 millimeters or less.

By forming the semiconductor device in a shape of sphere,
the resistance to the external stress will be further increased
more than a cube form, because no corner exists.

In particular the application of the semiconductor device
20 to a thin electronic device including IC cards, tags, and
valuables will be allowed when forming the external dimension
of the semiconductor device (length of an edge for a cube and
a chip, or diameter for a sphere) equal to or less than 0.5
millimeters.

25 By providing an optical shielding member on the

semiconductor chip, the effect influenced by the incident light to the semiconductor device on the electron-hole pairs may be avoided.

By means of a sheet material having a light shield characteristics for the shield material, the influence by the incident light may be positively avoided. By using printing ink for the shield material, the shield may be formed in an inexpensive manner.

To achieve the yet another object of the present invention, the method in accordance with the present invention comprises the steps of: providing a wall pattern onto the part corresponding to the separating region between semiconductor devices in a semiconductor substrate having a plurality of semiconductor devices; forming a support member having a certain mobility and allowing a bonding after curing onto the part corresponding to the semiconductor devices; and splitting the semiconductor device part into chips.

The mobility of the support member before curing allows the supply at once of the support member to a plurality of inner wall regions surrounded by the wall patterns, therefore improves the productivity. The support member, which can be melted after curing, is particularly suitable to thinner electronic devices because after assembly into an electronic device the member can be melted to reduce the thickness.

By screen-printing of the support member, a mass production

will be allowed at a less cost.

By means of a support member of a photosensitive material, the controllability of shapes inherent will allow a mass production.

5 The above and further objects and novel features of the present invention will more fully appear from following detailed description when the same is read in connection with the accompanying drawings. It is to be expressly understood, however, that the drawings are for the purpose of illustration
10 only and not intended as a definition of the limits of the present invention.

BRIEF DESCRIPTION OF THE DRAWINGS

20 DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS

[First embodiment]

A method of manufacturing a number of electronic devices by attaching a plurality of IC chips (thin chips) 17 onto a substrate 15 at once will be described in greater details by
25 referring to Figs. 1 (a) to 1 (d). In this embodiment, a

film-based substrate is used for the substrate 15. On the substrate 15 having some adhesive paste 14 applied, a registration jig (positioning frame) 12 having openings of the size corresponding to the IC chip 17 will be placed to supply
5 a plurality of IC chips 17 into the openings. The depth of the opening in the jig is preferably such that an opening houses one IC chip. When a support material 13 is provided, the size of the openings should include the thickness of the member. The depth should be enough to encompass the chip, because the portion
10 extending from the jig of an IC chip may be likely damaged by mechanically abrading with another IC chip if the opening has an insufficient depth. The supply of IC chip 17 to the opening can be performed by means of a vacuum sucker having a plurality of sucking ports each corresponding to the position of respective
15 of a plurality of openings, by attracting a plurality of IC chips at once. Fig. 1 (a) indicates a schematic cross-sectional view of thin chips 17 each having a support member 13 and each placed in the respective of openings of the registration jig 12 to fix onto a film base substrate 15 by means of suction and push-out
20 air 11. On the surface of thin chips a small antenna 16 for transmitting and receiving energy and data by means of radio frequency. A contactless electronic device may be thereby provided.

Fig. 13 is a plan view of registration to a jig, for aligning
25 thin chips 17 to the jig. The jig has a through hole or a recess

of the shape and size corresponding to the size of chip or a square. A thin chip will be fitted into the through hole or recess. The automatic registration will be performed while at the same time the mounting will be pressed to adhere automatically to the substrate.

Next, as shown in Fig. 1 (b), the positioning jig 12 will be removed.

Then, a covering sheet 19 will be placed through an adhesive material 18 (see Fig. 1 (c)).

Thereafter, the support member 36 will be melted to flow by applying heat and pressure to reduce the thickness of the electronic device (see Fig. 1 (d)). Then, the IC card substrate 15 will be cut so as to have the desirable number of thin IC chips 17 (one or more) to form an electronic device. In accordance with this method, the thin chip 17 will be stable during handling due to the support member 13. In the eventual form, the support member 13 will be deformed so as to conform to the thin shape and size of the final product. Since the IC chip 17 is thin, the chip may be curled due to the internal stress of the semiconductor material and is susceptible to the physical external stress, however by means of support member 13 as have been described above in this embodiment, a mechanical strength nearly equivalent to a thicker chip can be achieved so that a production of a number of thin chips at the same time will be allowed, with ease of handling, resulting in a significant

improvement of productivity.

[Second embodiment]

Now a method of attaching a support member to a thin chip
5 will be described in greater details by referring to Figs. 3
(a) to 3 (e).

Fig. 3 (a) is a schematic cross-sectional view of a
silicon-on-insulator type (SOI) wafer having a silicon substrate
31 (of thickness of approximately 200 micrometers), an oxide
10 layer 32 (of thickness of approximately 1 micrometer), and a
surface device layer 33 (of thickness of 0.5 to 10 micrometers)
having semiconductor IC devices formed in a manner well known
in the art.

Fig. 3 (b) is a schematic cross-sectional view during a
15 process of forming an oxide pattern 34 (of thickness of
approximately 0.5 micrometers) on the backside of the
silicon-on-insulator wafer. The oxide pattern 34 may also be
formed by a photolithograph as well known in the art. The oxide
pattern 34 will be formed in the region used for separating
20 semiconductor devices.

Fig. 3 (c) is a schematic cross-sectional view of the
process of etching the silicon by making use of the oxide pattern
formed thereon to leave the silicon sacrifice wall 35 and remove
the oxide. When using a SOI wafer, the oxide layer 32 is served
25 for a protection of silicon etching so as to provide a precise

control of the thickness of the silicon sacrifice wall 35.

However, when using an ordinary silicon substrate, the manufacturing cost can be lowered whereas the thickness controllability will be somewhat degraded when compared with a silicon-on-insulator wafer. Silicon can be processed in a shorter period of time by using a wet type etching method. On the other hand, the silicon can be processed with a higher precision of pattern by using a dry etching method. In the dry etching, the etching rate will be lower than the wet etching. Thus, the throughput may be improved by polishing the surface of the silicon substrate 31 or by previously thinning by means of the wet etching or the like.

Fig. 3 (d) is a schematic cross-sectional view indicating the support member 13 filled into the area from which the silicon has been removed (the area will correspond to the semiconductor IC devices region). The preferable support member 13 may be selected from a group of candidates, which will be melted and flowed by heating. For example, some examples of the support member 13 include wax and epoxy resin.

Fig. 3 (e) is a schematic cross-sectional view indicating the oxide layer 32 and the surface device layer 33 are removed by etching. By providing a size of the support member 13 larger than the semiconductor chip, the resistance to the external stress will be improved. In accordance with this method, the support member may be formed at a higher accuracy by selecting

an arbitrary support member material. In addition, the process will be performed on the wafer, allowing a further effect of providing a considerably excellent productivity.

It should be noted here that although in this embodiment
5 a silicon-on-insulator substrate is used, a substrate made of an ordinary silicon material may be used to render the process cost lower at the price of the variation of thickness of the IC chips.

10 [Third embodiment]

Another method of forming the support member 13 will be described in greater details by referring to Figs. 4 (a) to 4 (e).

First a silicon-on-insulator type wafer is provided having
15 a silicon substrate 31, an oxide layer 32, and a surface device layer 33 having semiconductor integrated circuit devices formed thereon (see Fig. 4 (a)).

The silicon substrate 31 will be etched to be removed (see Fig. 4 (b)). The oxide layer 32 will be served for a protector
20 of silicon etching.

Then, using a photo-resist technology, a photo-resist sacrifice wall 41 will be formed (see Fig. 4 (c)).

Thereafter a support member is filled between photo-resist sacrifice wall patterns 41 (see Fig. 4 (d)).

25 Thereafter, the oxide layer 32 and the surface device layer

33 will be etched to be removed (see Fig. 4 (e)). In accordance with this method, the support member may be formed at a higher accuracy with an arbitrary material selected. Since the process is performed on the wafer, the method will provide an effect of considerably excellent productivity. In this method the height of the wall pattern will be determined by the thickness of the resist layer, so that the range of adjusting the height will be narrower than the method in accordance with the second embodiment, however, the formation of the oxide layer 32 will be unnecessary, facilitating the photo-resist sacrifice wall 41 to be readily formed.

[Fourth embodiment]

An embodiment in which the electronic device is an IC card will be described in greater details by referring to Fig. 5. IC cards are used in a vast field of application, and it is anticipated that a number of cards in some fields will be disposable. Therefore, a significant consideration is needed on the thin chip equipped on an IC card film base 51 made of the film base described earlier. Fig. 5 is an embodiment of such an IC card. More specifically, a film base substrate in the size of a name card having chips mounted in a dispersed manner will allow the use of such a substrate as a card, provide a method of manufacturing IC cards at a considerably thinner card at a lower cost, and promote the use of such a card. By incorporating

an antenna into the thin IC chip 17, a contactless IC card can be yielded.

[Fifth embodiment]

5 Figs. 6 (a) and 6 (b) show another embodiment in accordance with the present invention. Fig. 6 (a) is an overview of a roll before cutting 61 having thin IC chips mounted thereon, which later will be sliced. The thin IC chips 17 are adhered onto the film based IC card substrate 15. Fig. 6 (b) is a roll 62
10 sliced to a predetermined width of the roll before cutting 61 not yet sliced as shown in Fig. 6 (a). Each chip is mounted on the sliced roll, allowing to use as a tape. By making a roll tape by slicing a large sheet incorporating a plurality of thin chips thereon, a mass production of electronic devices will be
15 provided.

[Sixth embodiment]

Fig. 7 shows an exemplary plan view of a thin IC chip 17 used in an embodiment in accordance with the present invention.
20 More specifically, a chip having an antenna 16 as shown in the figure will be effectively utilized in the present invention. An effective resonance circuit may be formed with an antenna 16 and a tuning capacitance 73 connected by a connection wiring 71 through a through hole 72. In the microwave band, the
25 inductance and capacitance may be sufficient to be very small

values, such as $4.2 \text{ pxn (H} \cdot \text{F)}$, so that a resonance circuit can be built with an extremely small inductor and a capacitor, allowing the formation of on-chip antenna to be effectively arranged. The present invention provides a method of manufacturing taking into consideration the economical efficiency.

Fig. 18 shows an example of a circuit formed in an IC chip. The circuit is a very promising one, which can be served for receiving microwave signals to transmitting data. This circuit has numerous features and characteristics such as converting the electromagnetic energy of the received microwaves into a direct current voltage, and receiving clock signals. By using microwaves, an antenna of a microscopic size of for example 300 micrometers square or less can be used for this purpose. Thereby an antenna is allowed to be incorporated in an IC chip.

By using a thin IC chip having an antenna as have been described above, a contactless electronic device will be provided.

[Seventh embodiment]

In this embodiment, another method of forming the support member 13 will be described in greater details by referring to Figs. 8 (a) to 8 (c). Fig. 8 (a) is a plan view of a silicon wafer 81. Fig. 8 (b) is a partially sectional view of a portion shown in Fig. 8 (a). In the cross-sectional view the silicon

wafer 81 is affixed on a supporting sheet 82, each chip is thinner and separated from each other. Fig. 8 (c) is a schematic cross-sectional view illustrating the support member 13 required in the present invention is formed by screen-printing. For the material a silver paste and conductive carbon ink may be used.

The efficiency of the present invention is in the formation of the support member at a lower cost. Screen-printing may allow the support member to be easily formed on a wafer.

[Eighth embodiment]

Fig. 9 shows still another preferred embodiment of the present invention. A thin chip as an inevitable mode of implementation is expected to be implemented in a thin form of product. The technology required in the implementation to be cited herein may include a protection of malfunctions by optics. A countermeasure for this purpose is shown in this figure, in which a light shield may be added on top and bottom of the antenna 16 formed on a thin IC chip 17 by means of an upper shield sheet 91 and a lower shield sheet 92. This may provide an electronic device, which is protected from the malfunctioning in a thinner chip.

By using a shield sheet having a larger surface area than the thin IC chip 17 the incident light may be effectively shaded. In addition, the shielding member may be formed at once on a wafer, prior to separating chips, to allow the cost to decrease.

Furthermore, the shielding members may be either on top or on bottom, depending on the application.

The shielding member formed by printing will further decrease the manufacturing cost.

5

[Ninth embodiment]

A method of shielding incident light will be further described by referring to Fig. 10. In Fig. 9, there are the upper shielding mask sheet 91 and the lower shielding mask sheet 10 92, which are formed on both sides of the thin IC chip 17 and the antenna 16 formed thereon, thereafter upper shielding mask ink 101 and lower shielding mask ink 102 will be formed thereon to have a functionality to complete the shield such that the top shielding sheet 91 and the bottom shielding sheet 92 do not 15 work sufficiently as expected due to the transparency. Ink may be provided as the printing patterns. This allows the shielding to be improved.

[Tenth embodiment]

20

A method of forming an electronic device by cutting a film in a form of roll tape having a plurality of IC chips mounted to separate to pieces, and attaching a piece to a medium will be described in greater details by referring to Figs. 11 (a) to 11 (c). Fig. 11 (a) is a schematic cross-sectional view of 25 an example arrangement of a tape cutter 111 and tape rollers

for outspreading the rolled tape in accordance with the present invention on a medium 113. Fig. 11 (b) is a schematic diagram of adhering the tape including thin chips onto the medium by means of the tape rollers. Fig. 11 (c) is the mating of a piece with the medium. In this embodiment, the tape including thin chips is so thinner that the adhesion to a medium will be performed without problem, allowing electronic devices to be manufactured in a bulk at a lower cost.

10 [Eleventh embodiment]

An example of use of the electronic device in accordance with the present invention will be described by referring to Fig. 12. An interrogator antenna 121 will transmit a radio frequency transmission 121 toward the IC chip 17, which is mounted on the IC card substrate 15, to feed the received radio frequency waves to the interrogator antenna 121 by means of an effective circuit technology. This can be implemented without a battery or power source, by obtaining the energy needed to operate the circuit from the interrogator antenna 121 to send back any data necessary to the interrogator. The thin IC chip may be attached to any type of mediums 113.

[Twelfth embodiment]

Another embodiment of forming a support member is shown in Figs. 15 (a) to 15 (c). After removing the silicon substrate

on the backside of the silicon-on-insulator substrate, a supporting sheet 82 will be attached on the side of the oxide layer 32. Then, on the surface side of the surface device layer 33 having semiconductor integrated circuit devices formed a resist layer 153 will be applied to the thickness of approximately 50 micrometers, then the irradiating beam 151 will be applied to the photosensitive material 153 through a photomask 152 (see Fig. 15 (a)). The thickness of the resist layer 153 may be in the range of approximately 5 to 100 micrometers. Thus the thinner the supporting effect is small, the thicker the layer is difficult to form. The accuracy of the size of patterns of the support member may be sufficient in the range of ± 5 micrometers or so.

Thereafter, the exposed area (corresponding to the chip separator area) will be developed to be removed (see Fig. 15 (b)).

Next, the surface device layer 33 in the area that the photosensitive material 153 has been removed will be removed (see Fig. 15 (c)). Fig. 16 shows a plan view. In Fig. 16 only a line of chips is shown for the sake of simplicity, however in a practical production a number of chips exist on a wafer (for example, 330,000 chips on a 8" wafer). As can be appreciated, by using the photosensitive material as the support member, the support can be easily formed on a wafer. The support member has another advantage in the aspect of efficiency that it can be formed by only one lithograph process on a wafer. By forming

thin chips equal to or less than approximately 10 micrometers, the resistance to the bending stress may be improved, at the price of difficulty in handling. However, a thinner chip with a support member attached in advance will considerably improve the processability of chips.

[Thirteenth embodiment]

Fig. 17 shows a wound roll of tape substrate 15 with the thin IC chips 17 mounted thereon. In the tenth, preferred embodiment as have been described above, the IC card substrate 15 with the thin chips 17 mounted thereon is cut to make pieces to install on another medium 113. In this embodiment the tape substrate 15 itself, which is cut to include required thin chips are used as the electronic device. A mottled whorl in this figure is the schematic cross-sectional view of the arrangement underlying the present invention. More specifically, the tape medium (in this embodiment the tape substrate itself) having thin IC chips 17 mounted thereon may be wounded like a roll of toilet tissue to be reeled without jag. Semiconductors mounted on a cellophane adhesive tape may be achieved at a very lower cost in accordance with the present invention, resulting in a potential to widely spread. A convenience may be significantly improved, by having intelligence with the equivalent handling to the usual scotch tapes.

[Fourteenth embodiment]

Figs. 19 (a) to 19 (d) show another embodiment in accordance with the present invention. In basics, this embodiment is similar to the first preferred embodiment as have been described above, however the IC card substrate 15 and the covering sheet 19 are replaced respectively with the bottom shielding sheet 92 and the top shielding sheet 91, both having the shield effect. This allows the shielding effect to be further improved to suppress or prevent the malfunctioning caused by the electron-hole pairs generated by the incident light.

The foregoing description of the preferred embodiments of the invention has been presented for purposes of illustration and description thereof. It is not intended to be exhaustive or to limit the invention to the precise form disclosed, and modifications and variations are possible in light of the above teachings or may be acquired from practice of the invention. The embodiments chosen and described in order to explain the principles of the invention and its practical application to enable one skilled in the art to utilize the invention in various embodiments and with various modifications as are suited to the particular use contemplated. it is intended that the scope of the invention be defined by the claims appended hereto, and their equivalents.

In accordance with the present invention, following effects may be expected. The reinforcement of thin chips allows

the manufacturing processes to be performed in a manner similar to those used for the ordinary thicker chips, the batch handling of thinner chips in bulk to be realized, as well as the productivity to be considerably increased. The support member which may melt and flow facilitate to provide a thinner electronic device.

It is further understood by those skilled in the art that the foregoing description is some preferred embodiments of the disclosed method and that various changes and modifications may be made in the invention without departing from the spirit and scope thereof.
